

Requirements

Select a dataset that is **not** time-series-based. Upload the dataset with your submission and confirm that it satisfies **all** of the following criteria:

1. Real data only

- **No fabricated, simulated, or AI-generated data** (e.g., ChatGPT-created tables are not allowed)

2. Data Requirements

- **Minimum of 10 variables (columns):** At least **6 continuous variables** and **2 to 4 categorical variables**, each with **no more than 3 categories**
- **Minimum of 500 observations (rows)**

3. Main continuous variable of interest

- Choose one key variable your team will investigate in depth (e.g. Airbnb rental price). The variable should remain interesting to explore when you convert it to a binary form (e.g. recoding Airbnb rentals as 1 if the nightly price exceeds \$250 and 0 if the price is \$250 or less).

As a team we would like to explore the price_total variable because every other variable should influence the total price, as well as providing a holistic view of the property's value.

4. Source transparency

- You must clearly cite the **exact source** of the data and how it was accessed

Source:

AirBnB. (2026, February). *AirBnB*. Kaggle. Retrieved July 15, 2026, from

<https://www.kaggle.com/datasets/youssefkhaled117/airbnb>

5. Each team member must contribute

- Describe each member's role in identifying, accessing, evaluating, or cleaning the data

Kennedy - Evaluating and accessing

Alex - Evaluating and cleaning

Helen - Identifying and accessing

6. Motivation & Goal

- Include a short paragraph (4–6 sentences) explaining:
 - **Why** your team chose this dataset
- - **What** you hope to learn or accomplish through analyzing it

Our team chose the “AirBnB” dataset because it contains a large amount of real world data as it has over 30 different variables and over 50,000 distinct rows (airbnb properties). From this we will be able to draw conclusions on why certain AirBnB properties are more valuable than others, or what features contribute most to their price. From this we could learn what aspects of a property that are most important for AirBnB owners to invest in in order to maximise revenues. On the converse we could also look at which types of properties often sit below the market average and could direct consumers to search for specific attributes in order to find cheaper AirBnB's in certain areas.

Submission Format: Upload Excel File.

Cleaning:

10 variables to keep:

total price (continuous)(variable of interest)

Is day (categorical)

Super host (categorical)

Is private (categorical)

Num_bedroom (continuous)

City (categorical)

Guest_satisfaction (continuous)

Safety_index (continuous)

Near an inexpensive_restaurant (continuous)

distance_city_center (continuous)
